❖ Splay Trees

Splay tree = one style of "self-balancing" tree ...

Splay tree insertion modifies insertion-at-root method:

- by considering **parent-child-grandchild** (three level analysis)
- by performing double-rotations based on p-c-g orientation

The idea: appropriate double-rotations improve tree balance.

Splay tree implementations also do **rotation-in-search**:

- can provide similar effect to periodic rebalance
- improves balance, but makes search more expensive

❖ ... Splay Trees

Cases for splay tree double-rotations:

- case 1: grandchild is left-child of left-child
- case 2: grandchild is right-child of left-child
- case 3: grandchild is left-child of right-child
- case 4: grandchild is right-child of right-child

❖ ... Splay Trees

Actions for splay tree double-rotations:

- case 1: grandchild is left-child of left-child
 - insert into left subtree, rotate right, rotate right
- case 2: grandchild is right-child of left-child
 - insert into left subtree, rotate left, rotate right
- case 3: grandchild is left-child of right-child
 - insert into right subtree, rotate right, rotate left
- case 4: grandchild is right-child of right-child
 - insert into right subtree, rotate left, rotate left

❖ ... Splay Trees

Example: double-rotation case for left-child of left-child:

❖ ... Splay Trees

Example: double-rotation case for right-child of left-child:

COMP2521 20T2 ♦ Splay Trees [5/14]

❖ Splay Tree Insertion Algorithm

In describing splay trees, it is convenient to use abbreviations

```
t1  = tr->left = left(tree)
tr  = tree->right = right(tree)
t1l = tree->left->left
t1r = tree->left->right
trr = tree->right->right
trl = tree->right->left
```

These could be implemented using **#define** in C, e.g.

```
#define t1l  t->left->left
```

❖ ... Splay Tree Insertion Algorithm

Algorithm for splay tree insertion:

```

insertSplay(tree,item):
    Input  tree, item
    Output tree with item splay-inserted

    if tree is empty then return new node containing item
    else if item=data(tree) then return tree
    else if item < data(tree) then
        if left(tree) is empty then
            left(tree) = new node containing item
        else if item < data(left(tree)) then
            // Case 1: left-child of left-child
            tll = insertSplay(tll,item)
            tree = rotateRight(tree)
        else // Case 2: right-child of left-child
            tlr = insertSplay(tlr,item)
            left(tree) = rotateLeft(left(tree))
        end if
        return rotateRight(tree)
    else if item > data(tree) then
        if right(tree) is empty then
            right(tree) = new node containing item
        else if item < data(right(tree)) then
            // Case 3: left-child of right-child
            trl = insertSplay(trl,item)
            right(tree) = rotateRight(right(tree))
        else // Case 4: right-child of right-child
            trr = insertSplay(trr,item)
            tree = rotateLeft(tree)
        end if
        return rotateLeft(tree)
    end if
end if

```

❖ Insertion into Splay Trees

Example: insert **18** into this splay tree:

❖ ... Insertion into Splay Trees

New node is moved to root via right then left rotation

❖ Searching in Splay Trees

Searching in splay trees:

```
searchSplay(tree,item):  
|   Input   tree, item  
|   Output address of item if found in tree  
|           NULL otherwise  
  
|   if tree=NULL then  
|       return NULL  
|   else  
|       tree = splay(tree,item)  
|       if data(tree)=item then  
|           return tree  
|       else  
|           return NULL  
|       end if  
|   end if
```

splay() is similar to **insertSplay()**, but doesn't add a node

moves **item** to root if found, moves nearest node to root if not found

❖ ... Searching in Splay Trees

Example: search for **22** in the splay tree

How does this affect the tree?

❖ ... Searching in Splay Trees

Found node is moved to root via right then left rotations

❖ Splay Tree Performance

Analysis of splay tree performance:

- assume that we "splay" for both insert and search
- consider: m insert+search operations, n nodes
- total number of comparisons: average $O((n+m) \cdot \log_2(n+m))$

Derivation of the above beyond the scope of this course.

❖ ... Splay Tree Performance

Implications of performance analysis

- no guarantee that cost of each operation is efficient
- but overall cost of operations is efficient

i.e. gives good overall (amortized) cost.

- insert cost not significantly different to insert-at-root
- search cost increases, but ...
 - tends to improve balance on each search
 - moves frequently accessed nodes closer to root

But still has worst-case search cost $O(n)$
